What Are Prime Numbers? I

Definition: Prime number

A *prime number* is a number that has exactly two divisors.

What Are Prime Numbers? II

Example:

- 2 is prime (two divisors: 1 and 2).
- 3 is prime (two divisors: 1 and 3).
- 4 is not prime (three divisors: 1, 2, and 4).

Theorem: Prime numbers

There is no largest prime number.

Proof:

1. Suppose *p* were the largest prime number.

Proof:

- **1.** Suppose *p* were the largest prime number.
- **2.** Let q be the product of the first p numbers.

Proof:

- **1.** Suppose p were the largest prime number.
- **2.** Let *q* be the product of the first *p* numbers.
- **3.** Then q + 1 is not divisible by any of them.

Proof:

- **1.** Suppose *p* were the largest prime number.
- **2.** Let q be the product of the first p numbers.
- **3.** Then q + 1 is not divisible by any of them.
- **4.** But q + 1 is greater than 1, thus divisible by some prime number not in the first p numbers.

The proof used reductio ad absurdum.

FindPrimeNumbers

```
Input: an integer n > 1.
Let A be an array of Boolean values, indexed by
  integers 2 to n,
initially all set to true.
for i = 2, 3, 4, ..., not exceeding \frac{1}{3}
  if A[i] is true:
    for j = i2, i2+i, i2+2i, i2+3i, ..., not
       exceeding n:
      A[i] := false.
Output: all i such that A[i] is true.
